

**ECONOMICS OF ENERGY
INNOVATION AND
SYSTEM TRANSITION**

Lessons and principles for policymaking

Presentation to National Institute of Advanced Sciences
(NIAS, IISc Campus Bangalore), 5 December 2022

Michael Grubb, Professor of Energy and Climate Change, UCL
Strategy Director, *Economics of Energy Innovation and System Transition (EEIST)*
Convening Lead Author, IPCC Sixth Assessment Report – Mitigation

- Energy innovation: recent breakthroughs
- Case studies and lessons learned
- A broadened theory of innovation processes
- The stylized dynamics of transition
- The UK electricity transition
- A global view

Q: What two things do the following energy technologies have in common?

- Offshore oil extraction
- Shale gas
- Combined cycle gas turbines
- Solar PV
- Wind energy
- High efficiency lighting (LED lights)

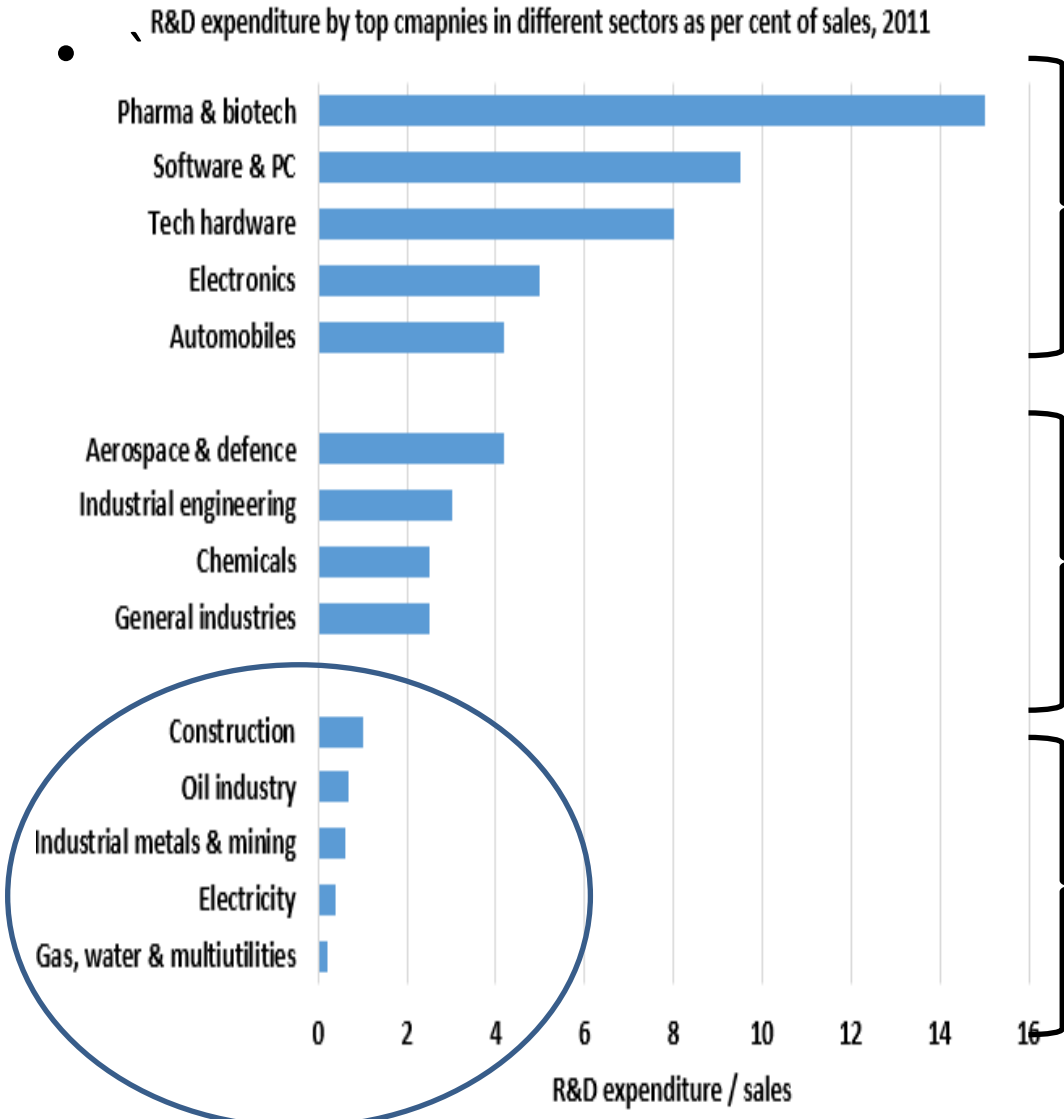

[1] They all turned out to be ***much cheaper*** than anyone expected

[2] They all involved government action at scale over many years

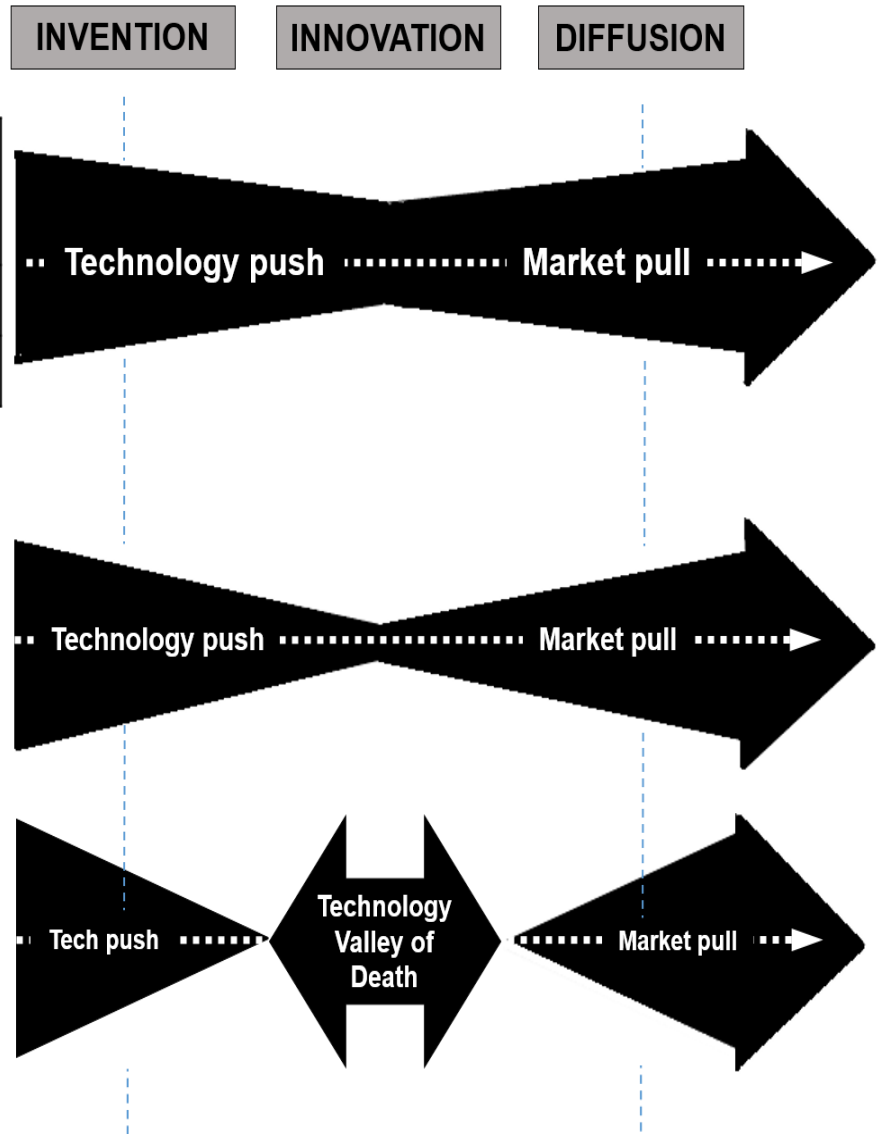

- *On both technology/resource development, and demand/price*

... some of the historically least innovative sectors of our economies

| |
|--|
| Highly innovating, closely connected consumers and innovators |
| 1 st and 3 rd Domains |
| Eg. IT and drugs sectors |
| Moderate innovation, within-business connections |
| 2 nd and 3 rd Domains |
| Eg. industrial and product engineering |
| Low innovation, little connection between innovators and markets |
| Eg. energy and construction industries |

“Solar power is by far the most expensive way of reducing carbon emissions

- *The Economist*, 2014.

“Germany is an example of how not to do green energy” - Bjorn Lomborg, *Financial Times* 2014

Solar power in Germany “makes as much sense as growing pineapples in Alaska.”

- J. Grossmann, then CEO of RWE AG in 2012

Wasn't growing solar pineapples in Alaska! *it was planting PV in the fertile soil of a country with the industrial capacity, financial structures, and political determination, to fund and forge a new industrial revolution*

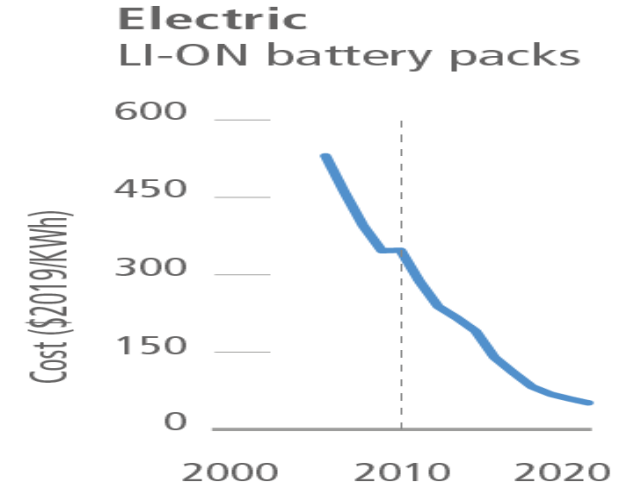

Innovation is *not* just R&D – but way beyond ...

PV is most dramatic – now at bottom of range of cost of new fossil fuel (like wind) ... but not the only one ..

ZHU SONGLI, PIM VERCOULEN, KAMNA WAGHRAY, ZHANG XILIANG

Key Findings

- Evidence
- Principles
- Implications

Evidence: Learning from Successes

Wind: from 1 to 10-15% in Brazil and Europe in a decade

Policy support 'both push and pull' – R&D, collaboration, industry-building, public-backed banks and contracts

Cumulative improvements

Globalisation of the *market*

Financial involvement crucial

Big breakthroughs also in offshore wind costs

Solar PV: from 'the most expensive' to 'the cheapest electricity in history'

Long evolution from R&D through niche commercialisation

Breakthroughs from strategic commitment driving market scale

Internationalisation of *production*

Prompting Chinese domestic ambition and globalisation of diffusion

Energy efficient lights: from high-tech gadgets to lighting the poor

Indian energy-efficiency institutions stimulated by Kyoto's Clean Development Mechanism

Linked to drive for 'modern energy services'

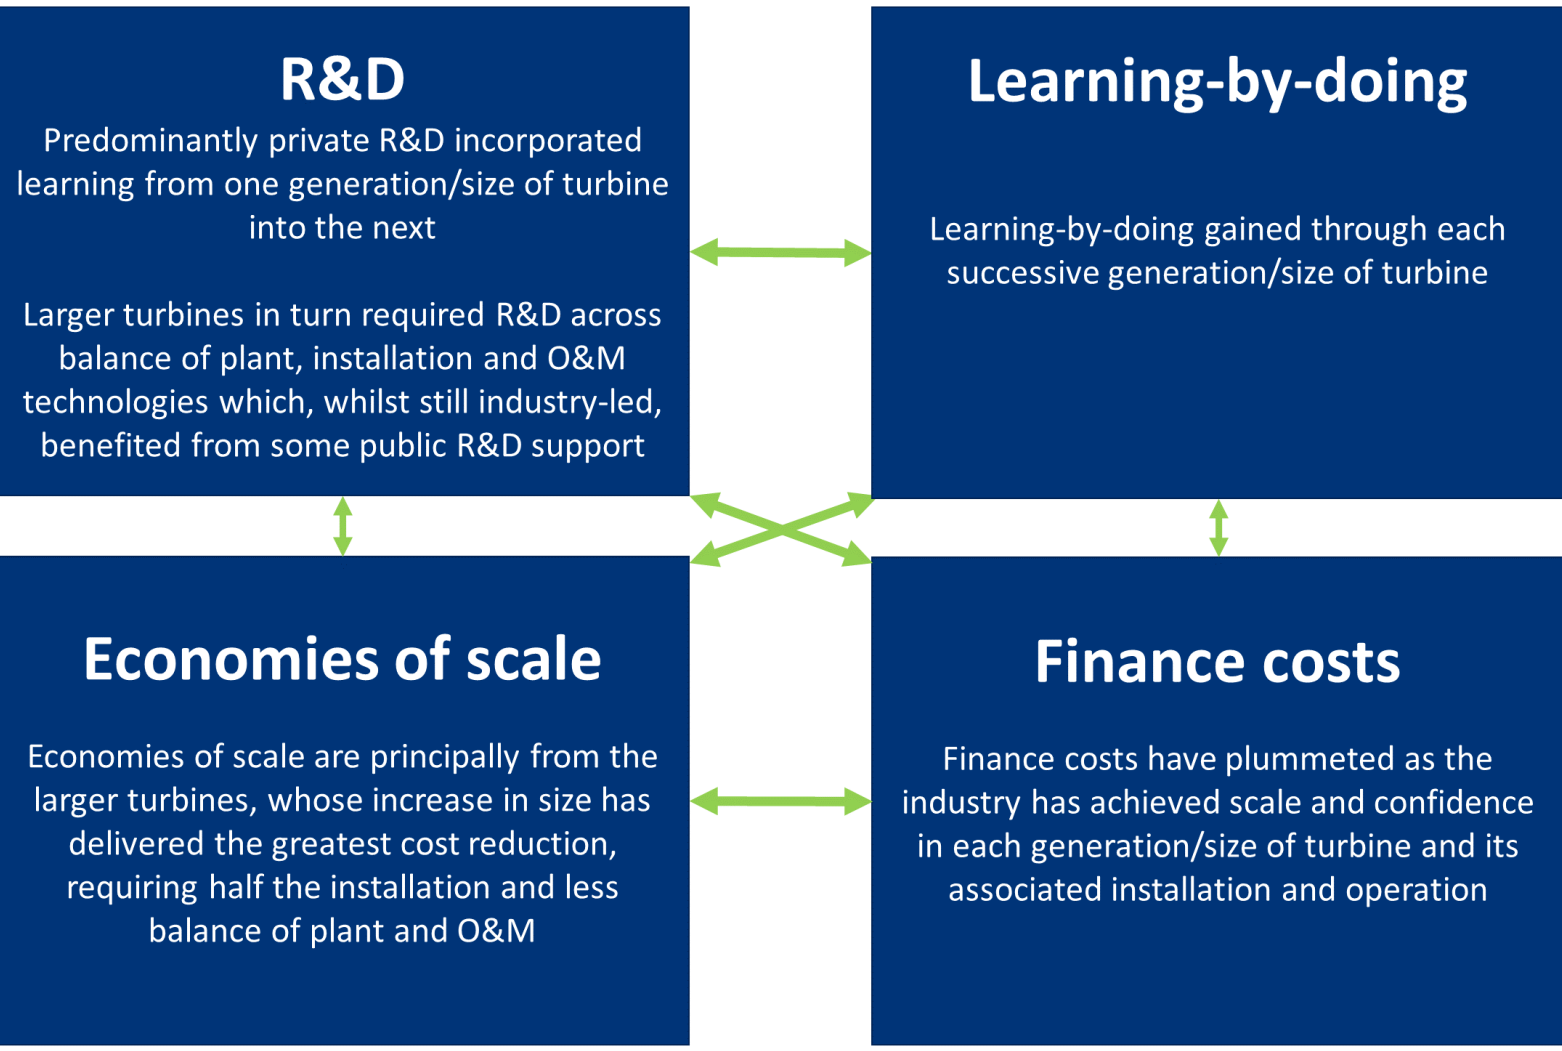

Bulk public procurement and smart policy through electricity suppliers drove **85% cost reduction in four years**

'The cheapest lighting in history'

UK Offshore wind - the components of cost reduction

Offshore wind in the UK – A remarkable success story

£170 MWh (2008) → £40 MWh (completion 2023)

Driven through strong, sustained and well-targeted **government support**

See: Jennings et al (2020) Policy, innovation and cost reduction in UK offshore wind, Carbon Trust, London

Big themes from case studies

- Led by strong government action; all are now largely self-sustaining
- Would not have been pursued under traditional economic cost-benefit assessment
- Common themes include:
 - **Cumulative progress.** Built upon previous progress, not blue-skies lab breakthroughs (innovation is '*cumulative*, and *path-dependent*')
 - **Market-based innovation.** market-based innovation and cost reduction, particularly associated with the deployment phase.
 - **Sustained and targeted support beyond R&D.** involved sustained support for deployment, mostly for 1-2 decades beyond the period dominated by public R&D.
 - **Substantial uncertainties,** at least in the earlier stages of deployment until critical thresholds were passed.
 - **Strong international dimensions.** It was indeed internationalisation that often sustained the growth of the technologies and helped them pass critical thresholds.

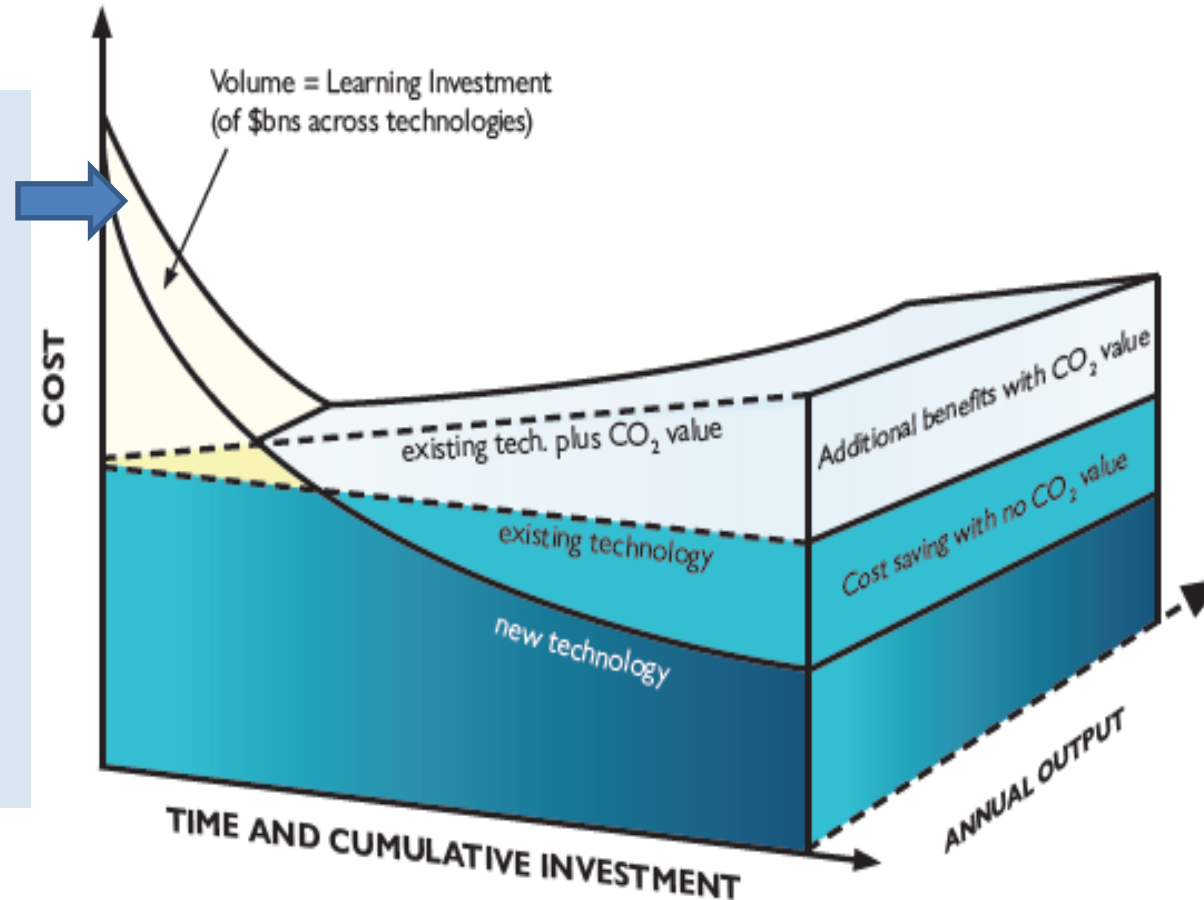

| Search-Links | Findings |
|--|---|
| <i>energy / carbon prices -> innovation indicators/outcomes</i> | <ul style="list-style-type: none"> - clear evidence of a positive link between energy price increases and patenting across these sectors – although strongest effects are usually lagged, often by several years - commonly path-dependent and based on previous knowledge stock – e.g. firms previously involved in ‘clean’ patenting (e.g. renewables, electric vehicles) vs. ‘grey’ patenting - induced incremental innovation (e.g. more efficient processes), and mostly when prices were high, or increasing stringency (and thus price) was expected in future. |
| <i>targeted policy -> innovation indicators/outcomes</i> | <ul style="list-style-type: none"> - Clear evidence Feed-in Tariffs (FiTs) induced patenting for solar PV - Renewable Portfolio Standards induced patenting in more mature renewables - Regulatory (i.e.energy & CO₂) standards induced patenting in energy efficient & low-carbon |
| <i>Learning Curves</i> | <ul style="list-style-type: none"> - Unambiguous correlation between deployed scale and cost reduction in almost all of > 1000 studies, reasonable evidence of causal relationship scale -> cost reduction |
| <i>Macro -> Outcomes</i> | <ul style="list-style-type: none"> - Oil shocks switched technical change from energy-increasing to energy-saving. “by 2000, 40% of fall in aggregate energy intensity attributable to induced technical change” - Asymmetric price elasticities (‘what goes down doesn’t necessarily come back up ...’) .. “almost all of the preferred models for OECD industrial energy demand incorporate both a stochastic underlying energy demand trend and asymmetric price responses” |

BOTTOM LINE: “HICKS (1932) WAS RIGHT”: Induced Innovation is real and important

Innovation beyond RD&D - can be costly but the returns can be huge, particularly when integrated with energy/externality pricing

North-Sea oil investments in the 1970s cost UK c.£100bn, remarkable cost reductions emerged

Offshore wind, a similar story, but driven by UK government (not OPEC!)

Rising carbon price could

Help fund innovation

Shift capital from clean to dirty

Give strategic direction

(but could never have driven the breakthroughs)

Both costs and benefits come with sizeable up-front uncertainties

THE SHAPE AND PACE OF CHANGE IN THE ELECTRICITY TRANSITION:

Sectoral dynamics and indicators of progress

Wind installed capacity and generation – historic trend and S-curve projections

Notes: Historic values for 2000-2019, from IRENA (2020a) and BP (2020). S-curve projections start from 2010 values. Saturation point of S-curves set at relevant 2050 Paris-consistent benchmark. Left-hand panel shows capacity, right-hand panel shows generation. Call-outs focus on 2000-2020.

Solar PV installed capacity and generation – historic trend and S-curve projections

Subsequent report (*Shape and pace of change in transport*) also identified exponential growth in electric vehicles, and traced implications

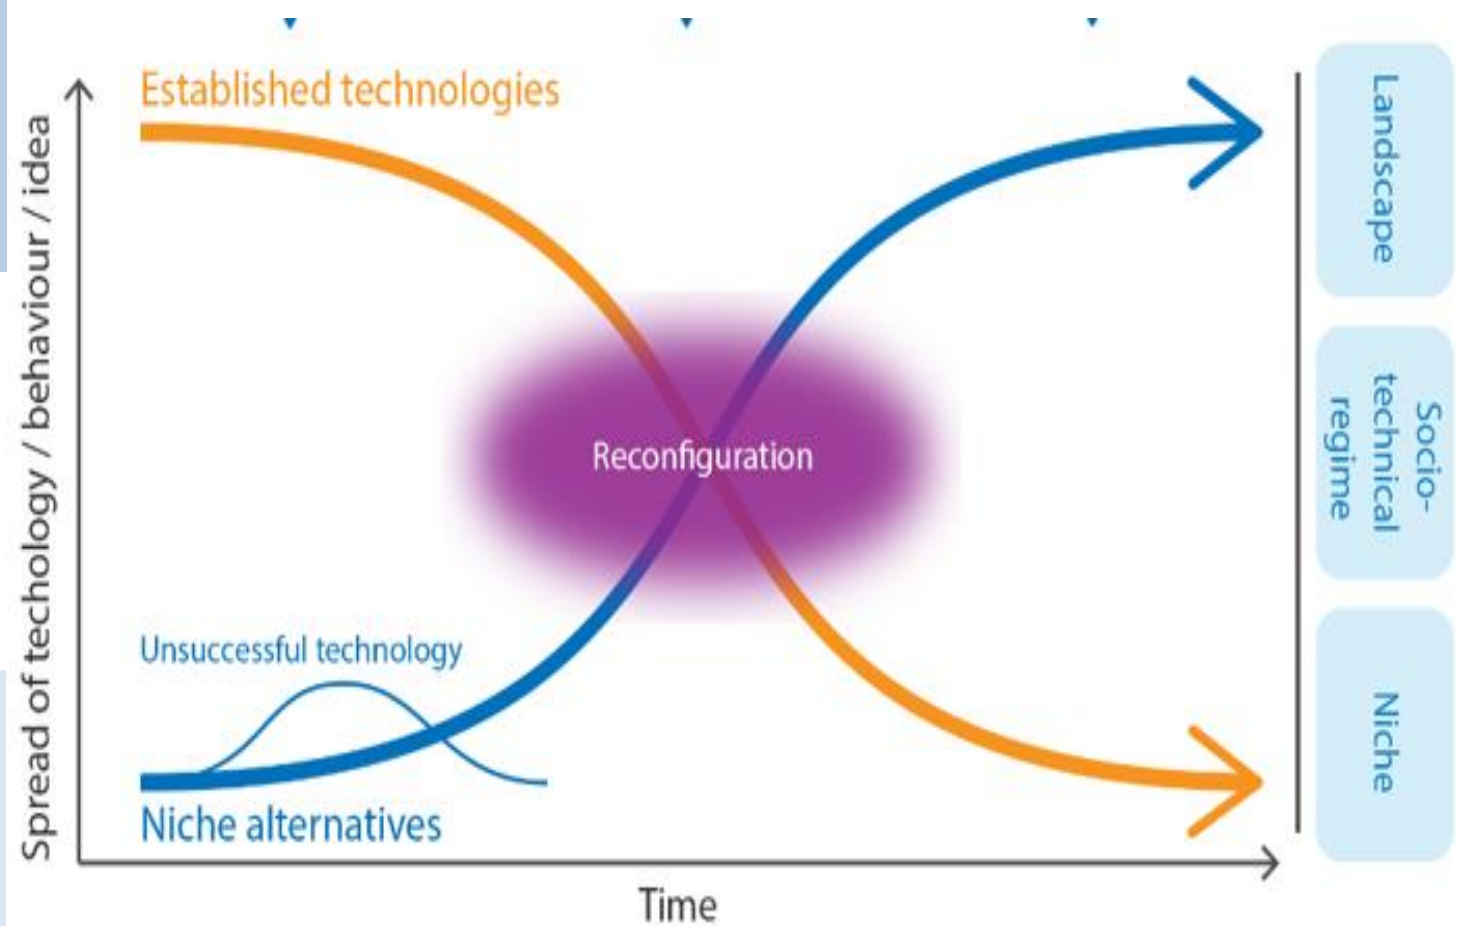

Notes: Historic values from 2000-2019, from IRENA (2020a). S-curve projections start from 2010 values. Saturation point of S-curves set at relevant 2050 Paris-consistent benchmark. Left-hand panel shows capacity, right-hand panel shows generation. Call-outs focus on 2000-2020.

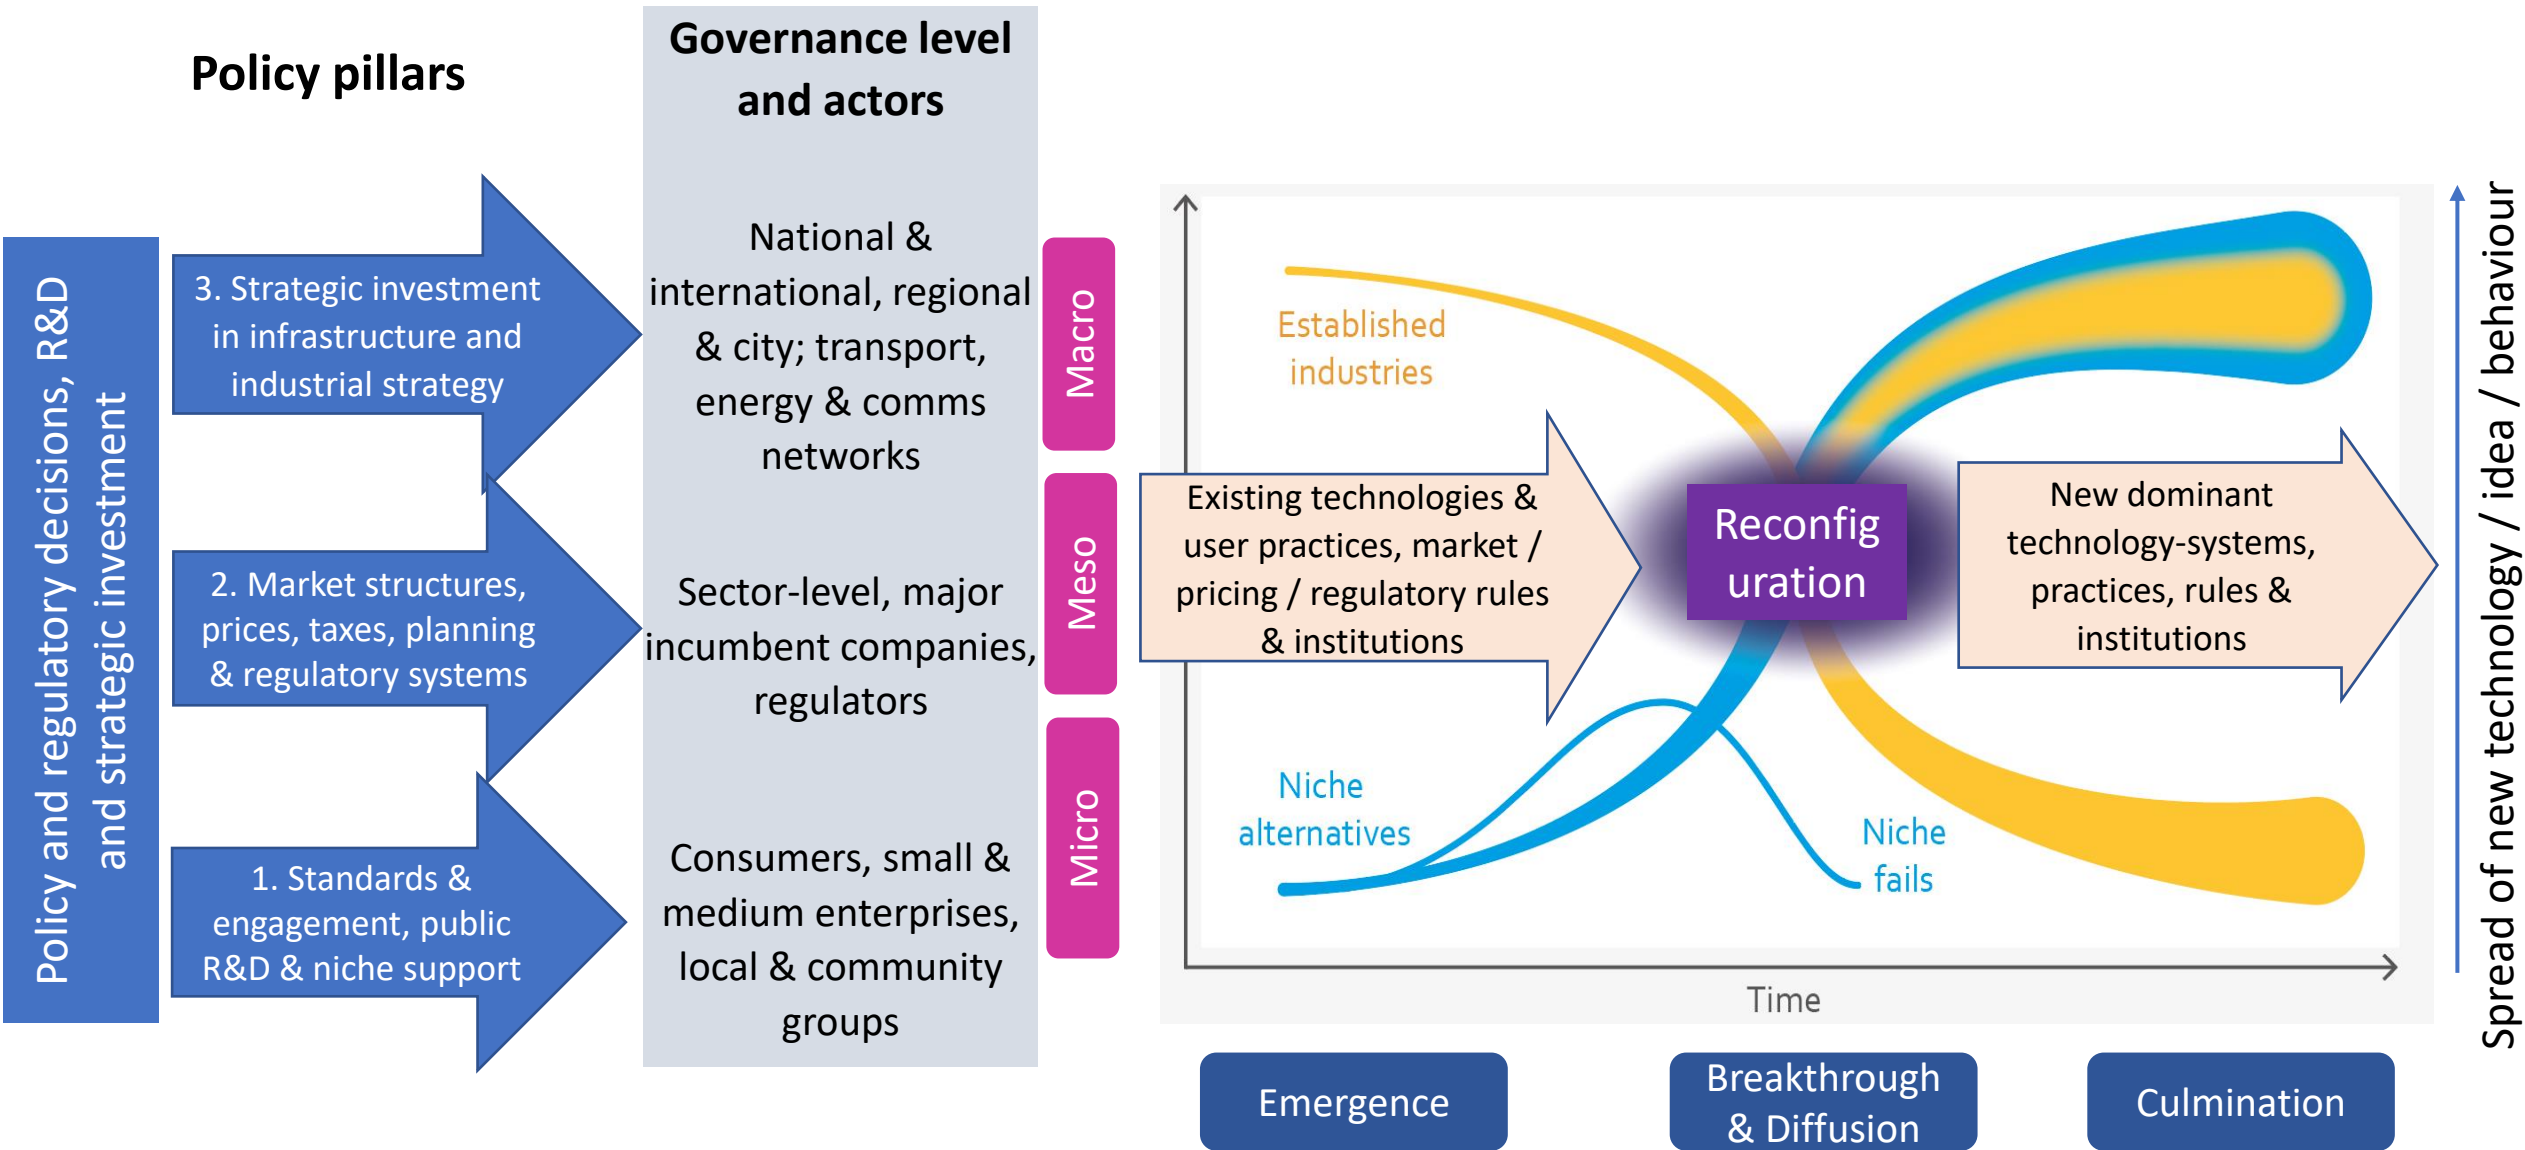

Impact on incumbent technologies / businesses initially modest, but ...

.... over time may involve substantial reconfiguration of existing infra/market structures

May start small, and take many years, *technology* emergence followed by *market* emergence

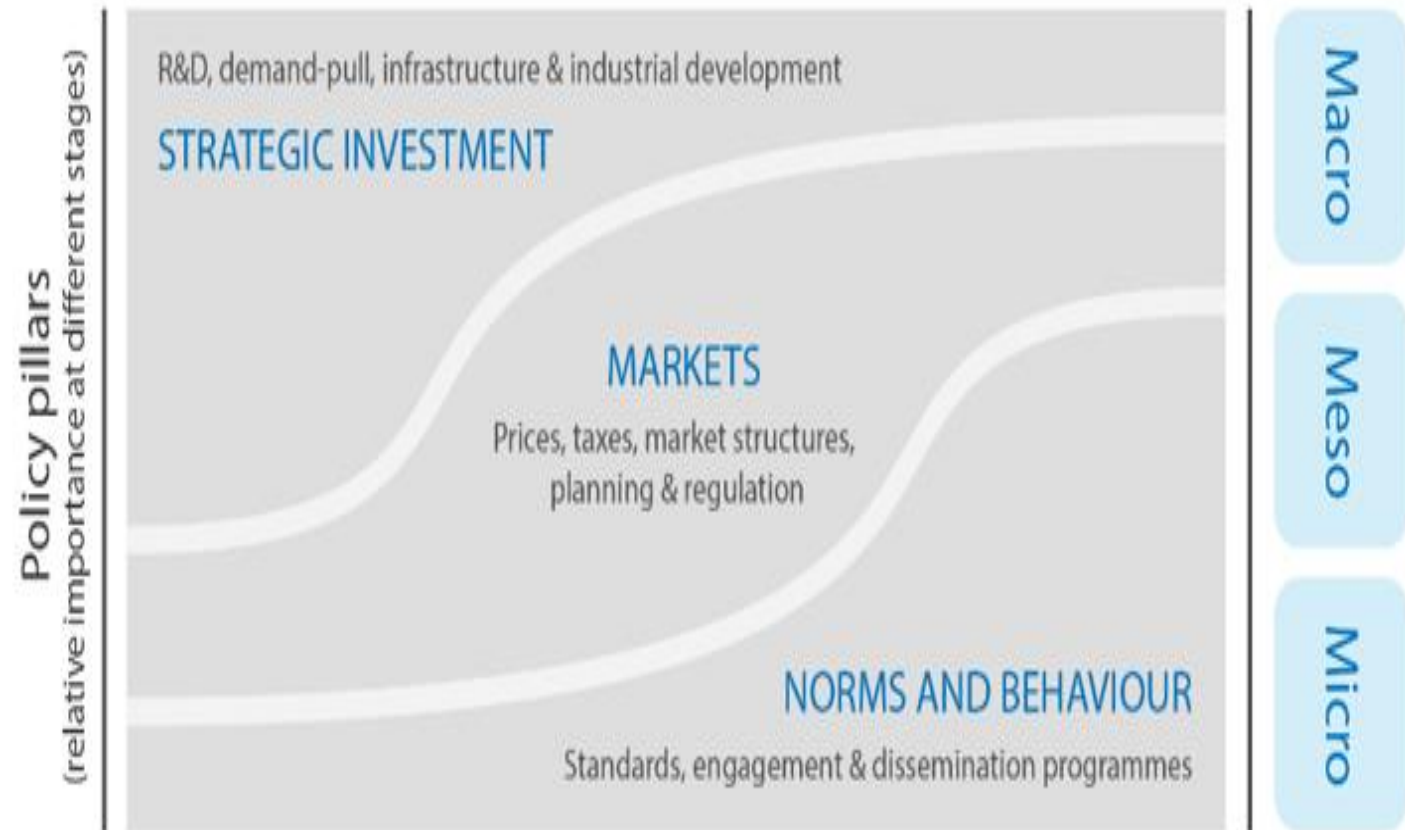

Transition dynamics: levels, policies and processes

For industrial transformation – *how do we get a price in the system, and [how] can we manage the revenues effectively?*

A mix of complementary policy instruments, evolving with transition

- Strategic Investment to foster emerging technologies and businesses, ‘leaders’
- Evolve or reconfigure infrastructure, market structures suited to new tech
 - scale in lead markets & supply chains
 - accelerate global diffusion
- Expand with attention to standards, norms, behaviour, to support widespread adoption and ‘laggards’

.. moved through a 'sea of gas', now rapidly rising renewables –

Four instruments

... with significant challenges in overall institutional design.

UK Coal Generation and Carbon Prices

UK power sector emissions **halved** since 1990, coal collapse.

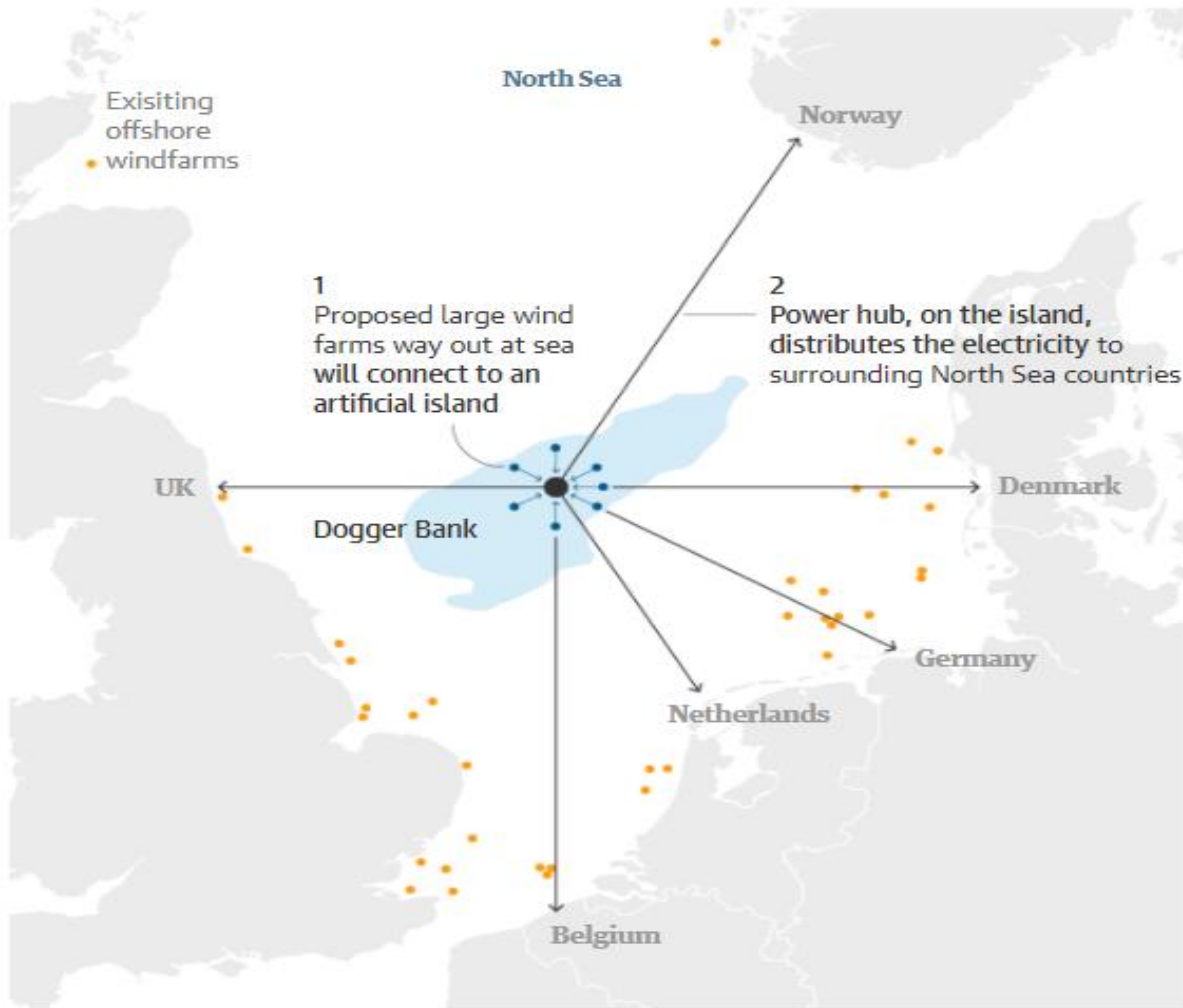

C price drives *operation and closure* not new investment or efficiency. Impact since 2014 much bigger than before due to price+ **and** :

- energy efficiency policies, demand declining since 2010
- Rapidly rising share of renewables: aim 50GW offshore for 2030

Trajectory for zero carbon electricity system by 2035

April 2017 - first hours without coal power for over a Century, driven by rising carbon price, declining gas price, and increasing renewables and efficiency. Now weeks at a time ..
UK total CO2 emissions now lower than a century ago, coal just occasional reserve

'Shallow' water?

Or floating ?

Note that for each individual windfarm, its curve is based on data starting from either January 2009, or from the date that the windfarm was fully commissioned, whichever is more recent. The curve for all windfarms is for the last five years.

INNOVATION AND
SYSTEM TRANSITION**

Lessons and principles for policymaking

Presentation to National Institute of Advanced Sciences
(NIAS, IISc Campus Bangalore), 5 December 2022

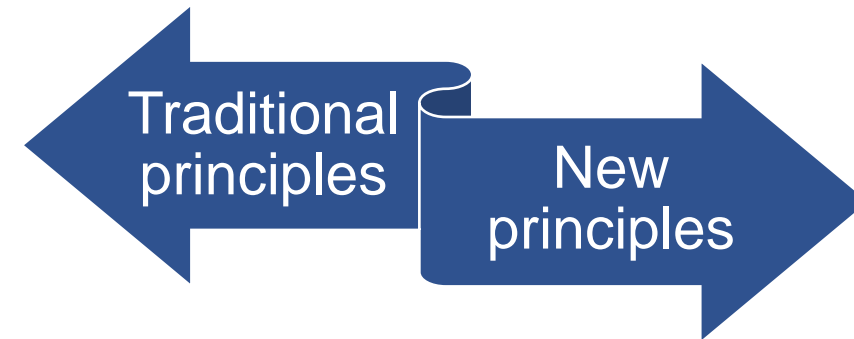

Michael Grubb, Professor of Energy and Climate Change, UCL
Strategy Director, *Economics of Energy Innovation and System Transition (EEIST)*
Convening Lead Author, IPCC Sixth Assessment Report – Mitigation

- Energy innovation: recent breakthroughs
- Case studies and lessons learned
- A broadened theory of the ‘innovation chain’
- The stylized dynamics of transition
- The UK electricity transition
- **A global view**

In the context of dynamic processes and structural change like the energy transition, **new general principles for policymaking are needed.**

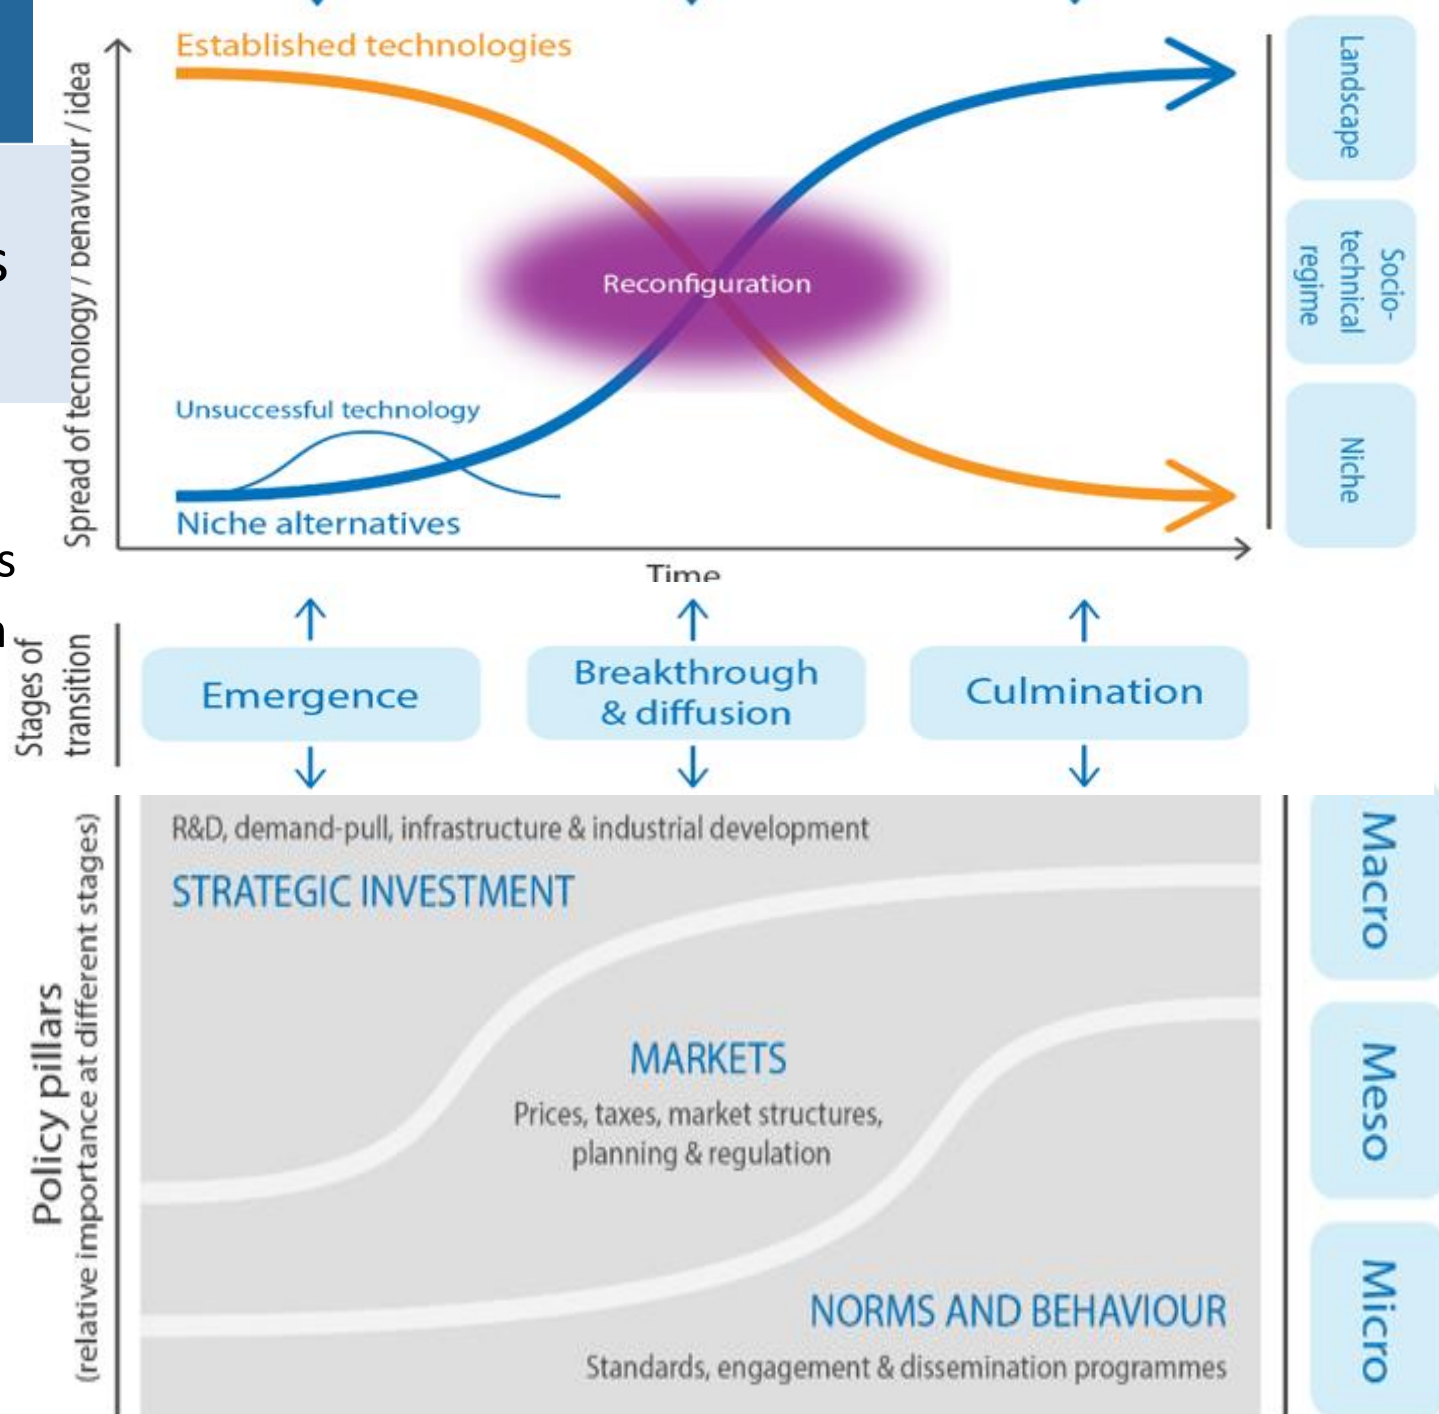

This New Principles are built on a wealth of **experience and analysis gathered over the last three decades** where policy has induced rapid innovation and growth in clean energy technologies.

Conclusions

Innovations take investment, experimentation, can lead to transitions with *evolution of policy packages*

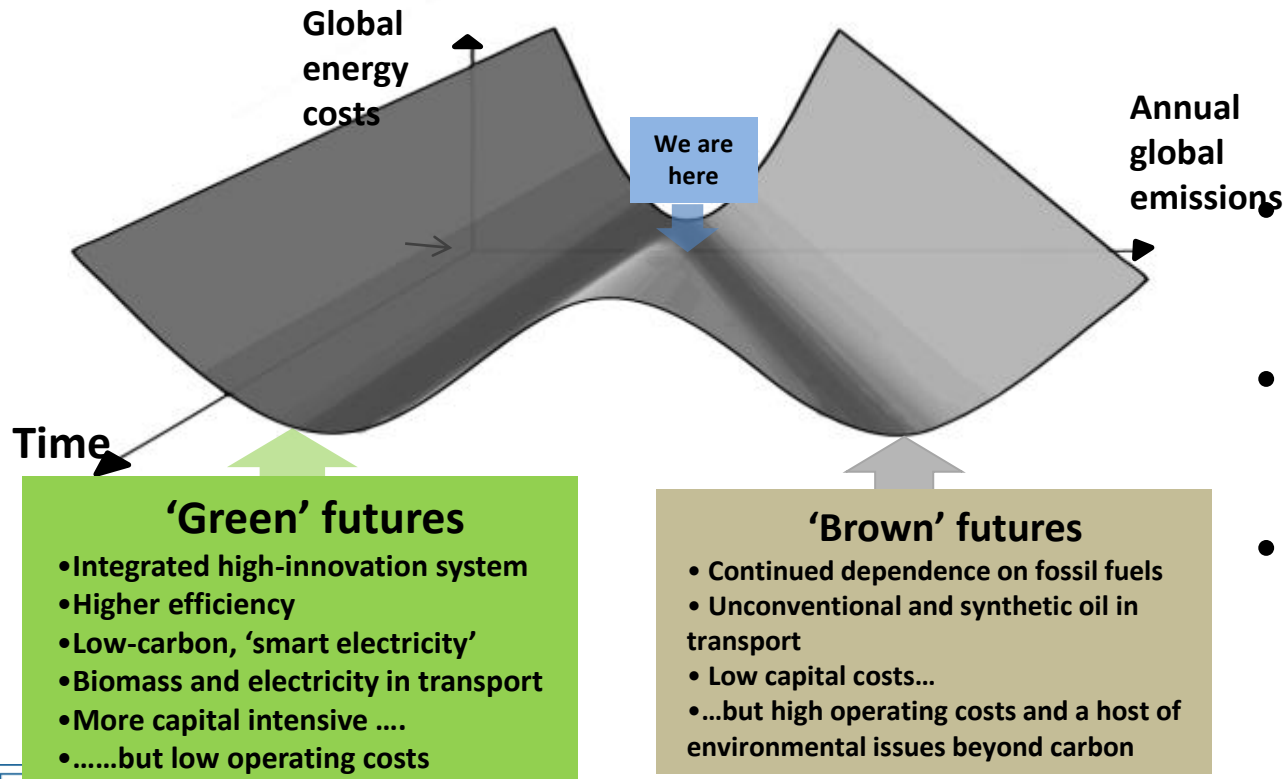

- The “10 principles” reflect experience of sustained innovation in technologies *and* systems, ultimately leading to major transitions
- Opportunities obvious, risks arise not just from tech uncertainties but from incumbent interests and challenge of declining industries
- link with the qualitative transitions literature emphasises *reconfiguration*
- ... and potential ‘tipping points’ into new systems
- Transitions require *policy combinations that also need to evolve*
- **With imagination, experimentation, commitment and investment, we can create very different, low-carbon energy futures**

‘Ignoranti quem portum petat nullus suus ventus est’ -

Lucius Annaeus Seneca

*No wind favours those who don't know
where they are going*

- 21st Century energy systems will be radically different from 20th Century
- Transition is already under way, so far driven far more by non-pure-market policies
- Need the Three Domains & associated Pillars of Policy designed as a mutually reinforcing package
- Harnessed for *industrial and development strategies*, “shifting development pathways”
- Including fresh consideration of carbon pricing as a *tool for change*
- Clear policy direction with all three pillars can shift risk, lower finance costs, and increase the economic gains from innovation and infrastructure

**ECONOMICS OF ENERGY
INNOVATION AND
SYSTEM TRANSITION**

Lessons and principles for policymaking

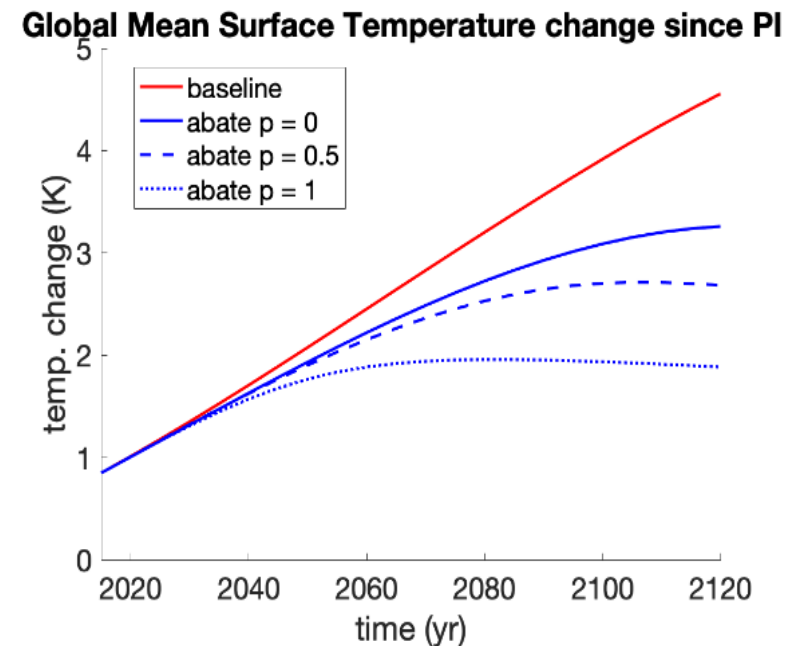

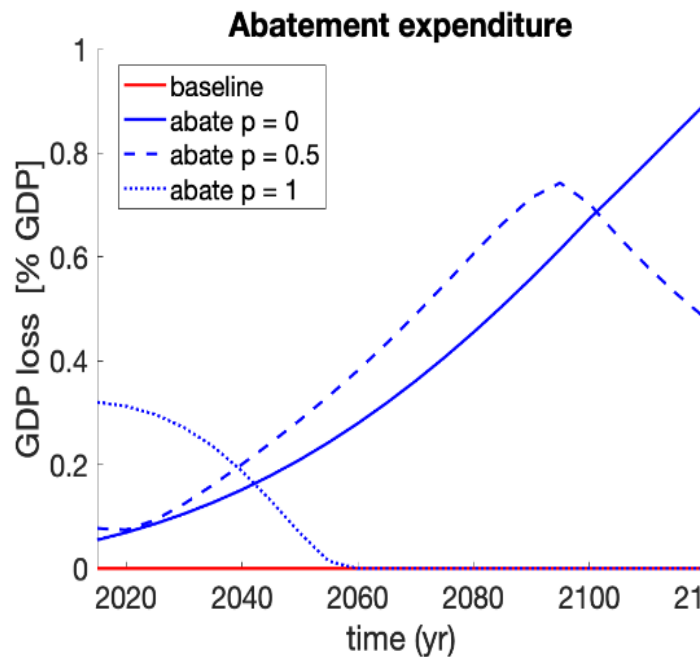

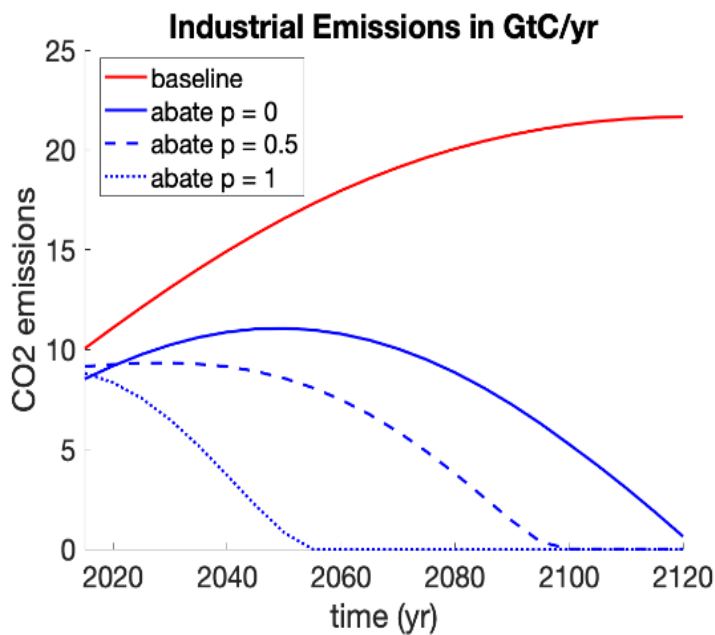

Presentation to National Institute of Advanced Sciences
(NIAS, IISc Campus Bangalore), 5 December 2022

Michael Grubb, Professor of Energy and Climate Change, UCL
Strategy Director, *Economics of Energy Innovation and System Transition (EEIST)*
Convening Lead Author, IPCC Sixth Assessment Report – Mitigation

- Energy innovation: recent breakthroughs
- Case studies and lessons learned
- A broadened theory of innovation processes
- The stylized dynamics of transition
- The UK electricity transition
- A global view

Impact of system pliability and adjustment timescales on global abatement expenditure, emissions and temperature change in DICE-PACE.

With high pliability and relatively short 'half life' characteristic transition time, the optimal response comprises:

Abatement: approx. linear reduction, to near zero around mid-Century

Effort: about four times bigger than in classical case (> 0.3% GDP)

Outcome: instead of > 3 deg.C, stays under 2 deg.C global temp change

Source: Grubb and Weiners (2020), *Modelling Myths: On the need for dynamic realism in DICE and other equilibrium models of global climate mitigation*, in review at Wiley Interdisciplinary Reviews (WIREs) – Climate Change
